Stata tip 33: Sweet sixteen: Hexadecimal formats and precision problems

Nicholas J. Cox

n.j.cox@durham.ac.uk

Computer users generally supply numeric inputs as decimals and expect numerical outputs as decimals. But underneath the mapping from inputs to outputs lies software (such as Stata) and hardware that are really working with binary representations of those decimals. Much ingenuity goes into ensuring that conversions between decimal and binary are invisible to you, but occasionally you may see apparently strange side effects of this fact. This problem is documented in [U] **13.10 Precision and problems therein**, but it still often bites and puzzles Stata users. This tip emphasizes that the special hexadecimal format `%21x` can be useful in understanding what is happening. The format is also documented, but in just one place, [U] **12.5.1 Numeric formats**. Decimal formats such as `%23.18f` can also be helpful for investigating precision problems.

Binary representations of numbers, using just the two digits 0 and 1, can be difficult for people to interpret without extra calculations. The great advantage of a hexadecimal format, using base 16 (i.e., 2^4), is that it is closer to base 10 representations while remaining truthful about what can be held in memory as a representation of a number. It is conventional to use the decimal digits 0–9 and the extra digits a–f when base 16 is used. Thus a represents 10 and f represents 15. Hence, at its simplest, hexadecimal 10 represents decimal 16, hexadecimal 11 represents decimal 17, and so forth. (Think of 11 as $1 \times 16^1 + 1 \times 16^0$, for example.) In practice, we want to hold fractions and, as far as possible, some extremely large and extremely small numbers. The general format of a hexadecimally represented number in Stata is thus mXp , to be read as $m \times 2^p$. Thus if you use the format `%21x` with `display`, you can see examples:

```
. di %21x 1
+1.000000000000000X+000
. di %21x -16
-1.000000000000000X+004
. di %21x 1/16
+1.000000000000000X-004
```

You see that 1, -16 , and $1/16$ are, respectively, 1×2^0 , -1×2^4 , and 1×2^{-4} .

The special format is useful to others besides the numerical analysts mentioned in [U] **12.5.1 Numeric formats**. If you encounter puzzling results, looking at the numbers in question should help clarify what Stata is doing and why it does not match your expectation.

Users get bitten in two main ways. First, they forget that most of the decimal digits .1, .2, .3, .4, .5, .6, .7, .8, and .9 cannot be held exactly. Of these, only .5 (1/2) can possibly be represented exactly by a binary approximation; all the others must be held approximately only—regardless of how many bytes are used. To convince yourself of this, see that, e.g., 42.5 can be held exactly,

```
. di %21x 42.5
+1.5400000000000X+005
. di (1 + 5/16 + 4/256) * 2^5
42.5
```

whereas 42.1 cannot be held exactly,

```
. di %21x 42.1
+1.50cccccccccdX+005
. di %23.18f 42.1
42.10000000000001421
```

Close, but not exact. Second, users forget that although very large or very small numbers can be held approximately, not all possible numbers can be distinguished, even when those numbers are integers within the limits of the variable type being used.

A common source of misery is trying to hold nine-digit integers in numeric variables. If these are identifiers, holding them as `str9` variables is a good idea, but let us focus on what often happens when users read such integers into numeric variables. This experiment shows the problems that can ensue.

```
. gen pinid = 123456789
. di %9.0f pinid[1]
123456792
. di %21x pinid[1]
+1.d6f346000000X+01a
```

Stata did not complain, but it did not oblige. The value is off by 3. You will see that the value held is a multiple of 4, as the last two digits 92 are divisible by 4. Did we or Stata do something stupid? Can we fix it?

```
. replace pinid = pinid - 3
(0 real changes made)
```

Trying to subtract 3 gives us the same number, so far as Stata is concerned. What is going on? By default, Stata is using a `float` variable. See [D] **data types** if you want more information. At this size of number, such a variable can hold only multiples of 4 exactly, so we lose many final digits. The remedy, if a numeric variable is needed, is to use a `long` or `double` storage type instead.
